

# Causal Interaction in Factorial Experiments: Application to Conjoint Analysis

Naoki Egami

Kosuke Imai

Princeton University

Talk for the Political Methodology Workshop

Stanford University

November 2, 2016

# Causal Heterogeneity and Interaction Effects

- Causal inference revolution in social sciences
  - Randomized experiments: laboratory, field, and survey experiments
  - Observational studies: natural experiments, research designs
- Many methods for estimating average treatment effect (ATE)
- Beyond ATE  $\rightsquigarrow$  Causal heterogeneity
  - ① Moderation:
    - How does the effect of a treatment vary across individuals?
    - Interaction between the treatment variable and pre-treatment covariates
  - ② Causal interaction:
    - What combination of treatments is efficacious?
    - Interaction among multiple treatment variables
  - ③ Individualized treatment regimes:
    - What treatment combination is optimal for a given individual?

# Factorial Experiments for Causal Interaction

- Causal interaction requires multiple treatments
- Randomized experiments with a **factorial design**
  - Factor = categorical variable with discrete values or “levels”
  - Example:  $2^2 \cdot 3 \cdot 4$  design (Gerber and Green, 2000)

- Factorial design is often used for audit studies and conjoint analysis

# Conjoint Analysis

- Survey experiments with a factorial design
- Respondents evaluate several pairs of randomly selected profiles defined by multiple factors
- Social scientists use it to analyze multidimensional preferences
- Example: Immigration preference (Hopkins and Hainmueller 2014)
  - representative sample of 1,407 American adults
  - each respondent evaluates 5 pairs of immigrant profiles
  - **gender**<sup>2</sup>, **education**<sup>7</sup>, **origin**<sup>10</sup>, **experience**<sup>4</sup>, **plan**<sup>4</sup>, **language**<sup>4</sup>, **profession**<sup>11</sup>, **application reason**<sup>3</sup>, **prior trips**<sup>5</sup>
  - What combinations of immigrant characteristics do Americans prefer?
  - High dimension: over 1 million treatment combinations
- **Methodological challenges:**
  - Many interaction effects  $\rightsquigarrow$  false positives, difficulty of interpretation
  - Very few applied researchers study interaction

# The Overview of the Talk

- ① New causal estimand: **Average Marginal Interaction Effect (AMIE)**
  - relative magnitude does not depend on baseline condition
  - intuitive interpretation even for high dimension
  - estimation using ANOVA with weighted zero-sum constraints
  - regularization done directly on AMIEs
- ② Comparison with the conventional interaction effect:
  - lack of invariance to the choice of baseline condition
  - difficulty of interpretation for higher-order interaction
- ③ Reanalysis of the conjoint analysis on ethnic voting in Africa

# Factorial Experiments with Two Treatments

- Two factorial treatments (e.g., gender and race):

$$A \in \mathcal{A} = \{a_0, a_1, \dots, a_{L_A-1}\}$$

$$B \in \mathcal{B} = \{b_0, b_1, \dots, b_{L_B-1}\}$$

- Assumption: **Full factorial design**

- ① Randomization of treatment assignment

$$\{Y(a_\ell, b_m)\}_{a_\ell \in \mathcal{A}, b_m \in \mathcal{B}} \perp\!\!\!\perp \{A, B\}$$

- ② Non-zero probability for all treatment combination

$$\Pr(A = a_\ell, B = b_m) > 0 \quad \text{for all } a_\ell \in \mathcal{A} \quad \text{and} \quad b_m \in \mathcal{B}$$

- Fractional factorial design not allowed

- ① Use a small non-zero assignment probability
- ② Focus on a subsample
- ③ Combine treatments

# Main Causal Estimands in Factorial Experiments

## ① Average Combination Effect (ACE):

- Average effect of treatment combination  $(A, B) = (a_\ell, b_m)$  relative to the baseline condition  $(A, B) = (a_0, b_0)$

$$\tau_{AB}(a_\ell, b_m; a_0, b_0) = \mathbb{E}\{Y(a_\ell, b_m) - Y(a_0, b_0)\}$$

- Effect of being Asian male

## ② Average Marginal Effect (AME; Hainmueller *et al.* 2014; Dasgupta *et al.* 2015):

- Average effect of treatment  $A = a_\ell$  relative to the baseline condition  $A = a_0$  averaging over the other treatment  $B$

$$\psi_A(a_\ell, a_0) = \int \mathbb{E}\{Y(a_\ell, B) - Y(a_0, B)\}dF(B)$$

- Effect of being male averaging over race

# The New Causal Interaction Effect

- **Average Marginal Interaction Effect (AMIE):**

$$\pi_{AB}(a_\ell, b_m; a_0, b_0) = \underbrace{\tau_{AB}(a_\ell, b_m; a_0, b_0)}_{\text{ACE of } (a_\ell, b_m)} - \underbrace{\psi_A(a_\ell, a_0)}_{\text{AME of } a_\ell} - \underbrace{\psi_B(b_m, b_0)}_{\text{AME of } b_m}$$

- Interpretation: additional effect induced by  $A = a_\ell$  and  $B = b_m$  together beyond the separate effect of  $A = a_\ell$  and that of  $B = b_m$
- Additional effect of being Asian male beyond the sum of separate effects for being male and being Asian
- Decomposition of ACE:  $\tau_{AB} = \psi_A + \psi_B + \pi_{AB}$
- **Invariance:** the *relative magnitude* of AMIE does not depend on the choice of baseline condition
- AMIEs depend on the distribution of treatment assignment:
  - ① specified by one's experimental design
  - ② motivated by a target population

# The Conventional Causal Interaction Effect

- **Average Interaction Effect (AIE):**

$$\xi_{AB}(a_\ell, b_m; a_0, b_0) = \mathbb{E}\{Y(a_\ell, b_m) - Y(a_0, b_m) - Y(a_\ell, b_0) + Y(a_0, b_0)\}$$

- Equal to linear regression coefficients
- Interactive effect interpretation (similar to AMIE):

$$\underbrace{\tau_{AB}(a_\ell, b_m; a_0, b_0)}_{\text{ACE of } (a_\ell, b_m)} = \underbrace{\mathbb{E}\{Y(a_\ell, b_0) - Y(a_0, b_0)\}}_{\text{Effect of } A = a_\ell \text{ when } B = b_0} - \underbrace{\mathbb{E}\{Y(a_0, b_m) - Y(a_0, b_0)\}}_{\text{Effect of } B = b_m \text{ when } A = a_0}$$

- Conditional effect interpretation:

$$\begin{aligned} & \mathbb{E}\{Y(a_\ell, b_m) - Y(a_0, b_m)\} - \mathbb{E}\{Y(a_\ell, b_0) - Y(a_0, b_0)\} \\ = & \mathbb{E}\{Y(a_\ell, b_m) - Y(a_\ell, b_0)\} - \mathbb{E}\{Y(a_0, b_m) - Y(a_0, b_0)\} \end{aligned}$$

- difference in effect of being male between Asian and White
- difference in effect of being Asian between male and female

# Comparison between AMIE and AIE

- AIE is NOT **invariant** to baseline category:

- 1 cannot compare regression coefficients
- 2 zero interaction when a baseline category is involved

$$\xi_{AB}(a_\ell, b_0; a_0, b_0) = \xi_{AB}(a_0, b_m; a_0, b_0) = 0 \quad \text{for all } \ell, m$$

- 3 cannot regularize regression coefficients
- AMIE and AIE are closely related:

- 1 Conditional effect as a function of AMIE

$$\mathbb{E}\{Y_i(a_\ell, b_0) - Y_i(a_0, b_0)\} = \psi_A(a_\ell; a_0) + \pi_{AB}(a_\ell, b_0; a_0, b_0)$$

- 2 AIE is a linear function of AMIEs

$$\xi_{AB}(a_\ell, b_m; a_0, b_0) = \pi_{AB}(a_\ell, b_m; a_0, b_0) - \pi_{AB}(a_\ell, b_0; a_0, b_0) - \pi_{AB}(a_0, b_m; a_0, b_0)$$

- 3 AMIE is also a linear function of AIEs
- 4 No causal interaction  $\rightsquigarrow$  zero AMIEs, zero AIEs

# Higher-order Causal Interaction

- $J$  factorial treatments with  $L_j$  levels each:  $\mathbf{T} = (T_1, \dots, T_J)$

- Assumptions:

- ① Full factorial design

$$Y(\mathbf{t}) \perp\!\!\!\perp \mathbf{T} \quad \text{and} \quad \Pr(\mathbf{T} = \mathbf{t}) > 0 \quad \text{for all } \mathbf{t}$$

- ② Independent treatment assignment

$$T_j \perp\!\!\!\perp \mathbf{T}_{-j} \quad \text{for all } j$$

- Assumption 2 is not necessary for identification but considerably simplifies estimation
- We are interested in the  $K$ -way interaction where  $K \leq J$
- We extend all the results for the 2-way interaction to this general case

# Higher-order Average Marginal Interaction Effect

- General definition: the difference between ACE and the sum of all lower-order AMIEs (first-order AMIE = AME)
- Example: 3-way AMIE,  $\pi_{1:3}(t_1, t_2, t_3; t_{01}, t_{02}, t_{03})$ , equals

$$\begin{aligned} & \underbrace{\pi_{1:3}(t_1, t_2, t_3; t_{01}, t_{02}, t_{03})}_{\text{ACE}} \\ & - \underbrace{\left\{ \pi_{1:2}(t_1, t_2; t_{01}, t_{02}) + \pi_{2:3}(t_2, t_3; t_{02}, t_{03}) + \pi_{1:3}(t_1, t_3; t_{01}, t_{03}) \right\}}_{\text{sum of all 2-way AMIEs}} \\ & - \underbrace{\left\{ \psi(t_1; t_{01}) + \psi(t_2; t_{02}) + \psi(t_3; t_{03}) \right\}}_{\text{sum of AMEs}} \end{aligned}$$

- Properties:
  - 1  $K$ -way ACE = the sum of all  $K$ -way and lower-order AMIEs
  - 2 Invariance to the baseline condition

# Difficulty of Higher-order AIEs

- Generalize the 2-way ATIE by marginalizing the other treatments  $\underline{\mathbf{T}}^{1:2}$

$$\xi_{1:2}(t_1, t_2; t_{01}, t_{02}) = \int \mathbb{E} \{ Y(t_1, t_2, \underline{\mathbf{T}}^{1:2}) - Y(t_{01}, t_2, \underline{\mathbf{T}}^{1:2}) \\ - Y(t_1, t_{02}, \underline{\mathbf{T}}^{1:2}) + Y(t_{01}, t_{02}, \underline{\mathbf{T}}^{1:2}) \} dF(\underline{\mathbf{T}}^{1:2})$$

- In the literature, the 3-way ATIE is defined as

$$\xi_{1:3}(t_1, t_2, t_3; t_{01}, t_{02}, t_{03}) \\ = \underbrace{\xi_{1:2}(t_1, t_2; t_{01}, t_{02} \mid T_3 = t_3)}_{\text{2-way AIE when } T_3 = t_3} - \underbrace{\xi_{1:2}(t_1, t_2; t_{01}, t_{02} \mid T_3 = t_{03})}_{\text{2-way AIE when } T_3 = t_{03}}$$

- Higher-order ATIEs are similarly defined sequentially
- This representation is based on the **conditional effect interpretation**
- Problem: conditional effect of conditional effects!

# Nonparametric Estimation of AMIE

## 1 Difference-in-means estimator

- estimate ACE and AMEs using the difference-in-means estimators
- estimate AMIE as  $\hat{\pi}_{AB} = \hat{\tau}_{AB} - \hat{\psi}_A - \hat{\psi}_B$
- higher-order AMIEs can be estimated sequentially
- uses the empirical treatment assignment distribution

## 2 ANOVA based estimator

- saturated ANOVA include all interactions up to the  $J$ th order
- weighted zero-sum constraints: for all factors and levels,

$$\sum_{\ell=0}^{L_A-1} \Pr(A_i = a_\ell) \beta_\ell^A = 0, \quad \sum_{\ell=0}^{L_A-1} \Pr(A_i = a_\ell) \beta_{\ell m}^{AB} = 0,$$
$$\sum_{m=0}^{L_B-1} \Pr(B_i = b_m) \beta_m^B = 0, \quad \sum_{m=0}^{L_B-1} \Pr(B_i = b_m) \beta_{\ell m}^{AB} = 0, \quad \text{and so on}$$

- AMIEs are differences of coefficients:

$$\mathbb{E}(\hat{\beta}_\ell^A - \hat{\beta}_0^A) = \psi_A(a_\ell; a_0), \quad \mathbb{E}(\hat{\beta}_{\ell m}^{AB} - \hat{\beta}_{00}^{AB}) = \pi_{AB}(a_\ell, b_m; a_0, b_0)$$

- can use any marginal treatment assignment distribution of choice

# Regularization via GASH-ANOVA

- Too many coefficients to be estimated  $\rightsquigarrow$  over fitting, false positives, difficult interpretation
- Need for regularization by collapsing levels and selecting factors
- **Grouping and Selection using Heredity in ANOVA** (Post and Bondell):

$$\sum_{\ell, \ell'} w_{\ell\ell'}^A \max\{\phi^A(\ell, \ell')\} + \sum_{m, m'} w_{mm'}^B \max\{\phi^B(m, m')\} \leq \underbrace{c}_{\text{cost parameter}}$$

where

$$\phi^A(\ell, \ell') = \underbrace{|\beta_{\ell}^A - \beta_{\ell'}^A|}_{\text{AME}} \cup \left\{ \bigcup_{m=0}^{L_B-1} \underbrace{|\beta_{\ell m}^{AB} - \beta_{\ell' m}^{AB}|}_{\text{AMIE}} \right\}$$

- The adaptive weight takes the following form:

$$w_{\ell\ell'}^A = \left[ (L_A + 1) \sqrt{L_A} \max\{\bar{\phi}^A(\ell, \ell')\} \right]^{-1}$$

where  $\bar{\phi}^A(\ell, \ell')$  is AMEs and AMIEs estimated without regularization

# Conjoint Analysis of Ethnic Voting in Africa

- Ethnic voting and accountability: Carlson (2015, *World Politics*)
- Do voters prefer candidates of same ethnicity regardless of their prior performance? Do ethnicity and performance interact?
- Conjoint analysis in Uganda: 547 voters from 32 villages
- Each voter evaluates 3 pairs of hypothetical candidates
- 5 factors: **Coethnicity**<sup>2</sup>, **Prior record**<sup>2</sup>, **Prior office**<sup>4</sup>, **Platform**<sup>3</sup>, **Education**<sup>8</sup>
- **Prior record** = No if **Prior office** = businessman  
↪ combine these two factors into a single factor with 7 levels
- Collapse **Education** into 2 levels: relevant degrees (MA in business, law, economics, development) and other degrees

# A Statistical Model of Preference Differentials

- ANOVA regression with one-way and two-way effects:

$$Y_i(\mathbf{T}_i) = \mu + \sum_{j=1}^J \sum_{\ell=0}^{L_j-1} \beta_{\ell}^j \mathbf{1}\{T_{ij} = \ell\} + \sum_{j \neq j'} \sum_{\ell=0}^{L_j-1} \sum_{m=0}^{L_{j'}-1} \beta_{\ell m}^{jj'} \mathbf{1}\{T_{ij} = \ell, T_{ij'} = m\} + \epsilon_i$$

with appropriate weighted zero-sum constraints

- In conjoint analysis, we observe the sign of preference differentials
- Linear probability model of preference differential:

$$\begin{aligned} & \Pr(Y_i(\mathbf{T}_i^*) > Y_i(\mathbf{T}_i^*) \mid \mathbf{T}_i^*, \mathbf{T}_i^*) \\ &= \mu^* + \sum_{j=1}^J \sum_{\ell=0}^{L_j-1} \beta_{\ell}^j (\mathbf{1}\{T_{ij}^* = \ell\} - \mathbf{1}\{T_{ij}^* = \ell\}) \\ & \quad + \sum_{j \neq j'} \sum_{\ell=0}^{L_j-1} \sum_{m=0}^{L_{j'}-1} \beta_{\ell m}^{jj'} (\mathbf{1}\{T_{ij}^* = \ell, T_{ij'}^* = m\} - \mathbf{1}\{T_{ij}^* = \ell, T_{ij'}^* = m\}) \end{aligned}$$

where  $\mu^* = 0.5$  if the position of profile does not matter

- We apply GASH-ANOVA to this model

# Ranges of Estimated AMEs and AMIEs

	Range	Selection prob.
<b>AME</b>		
Record	0.122	1.00
Coethnicity	0.053	1.00
Platform	0.023	0.93
Degree	0.000	0.33
<b>AMIE</b>		
Coethnicity $\times$ Record	0.053	1.00
Record $\times$ Platform	0.030	0.92
Platform $\times$ Coethnic	0.008	0.64
Coethnicity $\times$ Degree	0.000	0.62
Platform $\times$ Degree	0.000	0.35
Record $\times$ Degree	0.000	0.09

- Factor selection probability based on bootstrap

# Close Look at the Estimated AMEs

Factor	AME	Selection prob.
<b>Record</b>		
{ Yes/Village	0.122	} 0.71
{ Yes/District	0.122	
{ Yes/MP	0.101	} 0.77
{ No/Village	0.047	
{ No/District	0.051	} 0.74
{ No/MP	0.047	
{ No/Businessman	base	} 1.00
<b>Platform</b>		
{ Jobs	-0.023	} 0.56
{ Clinic	-0.023

<b>Coethnicity</b>	0.054	1.00
<b>Degree</b>	0.000	0.33

# Effect of Regularization on AMIEs

Without Regularization

With Regularization

# Decomposition and Conditional Effects

- Decomposition of ACE (Coethnicity  $\times$  Record interaction):

$$\begin{aligned} & \underbrace{\tau(\text{Coethnic, No/Business; Non-coethnic, No/MP})}_{-2.4} \\ = & \underbrace{\psi(\text{Coethnic; Non-coethnic})}_{5.4} + \underbrace{\psi(\text{No/Business; No/MP})}_{-4.7} \\ & + \underbrace{\pi(\text{Coethnic, No/Business; Non-coethnic, No/MP})}_{-3.1} \end{aligned}$$

- Conditional effects (Platform  $\times$  Record interaction):
  - AMIE:  $\pi(\text{Education, No/MP}; \{\text{Job, No/MP}\}) = -2.3$
  - Conditional effect of Education relative to Job for No/MP is approximately zero
  - AME:  $\psi(\text{Education; Job}) = 2.3$

# Concluding Remarks

- Interaction effects play an essential role in causal heterogeneity
  - ① moderation
  - ② causal interaction
- Randomized experiments with a factorial design
  - ① useful for testing multiple treatments and their interactions
  - ② social science applications: audit studies, conjoint analysis
  - ③ challenge: estimation and interpretation in high dimension
- **Average Marginal Interaction Effect (AMIE)**
  - ① invariant to baseline condition
  - ② straightforward interpretation even for high order interaction
  - ③ enables effect decomposition
  - ④ enables regularization through ANOVA
- Designing factorial experiments (work in progress)
  - ① select factors and levels via our method to reduce dimension
  - ② use unregularized ANOVA for the main study
